

Acrobatics to Squeeze Aerosols and Their
Direct Forcing from the CERES CRS Product

T. P. Charlock, Fred. G. Rose, David A. Rutan, Lisa H. Coleman, and W. Collins

Co-I Report to CERES STM (Newport News, 1-3 May 2001)

Essential starting points:

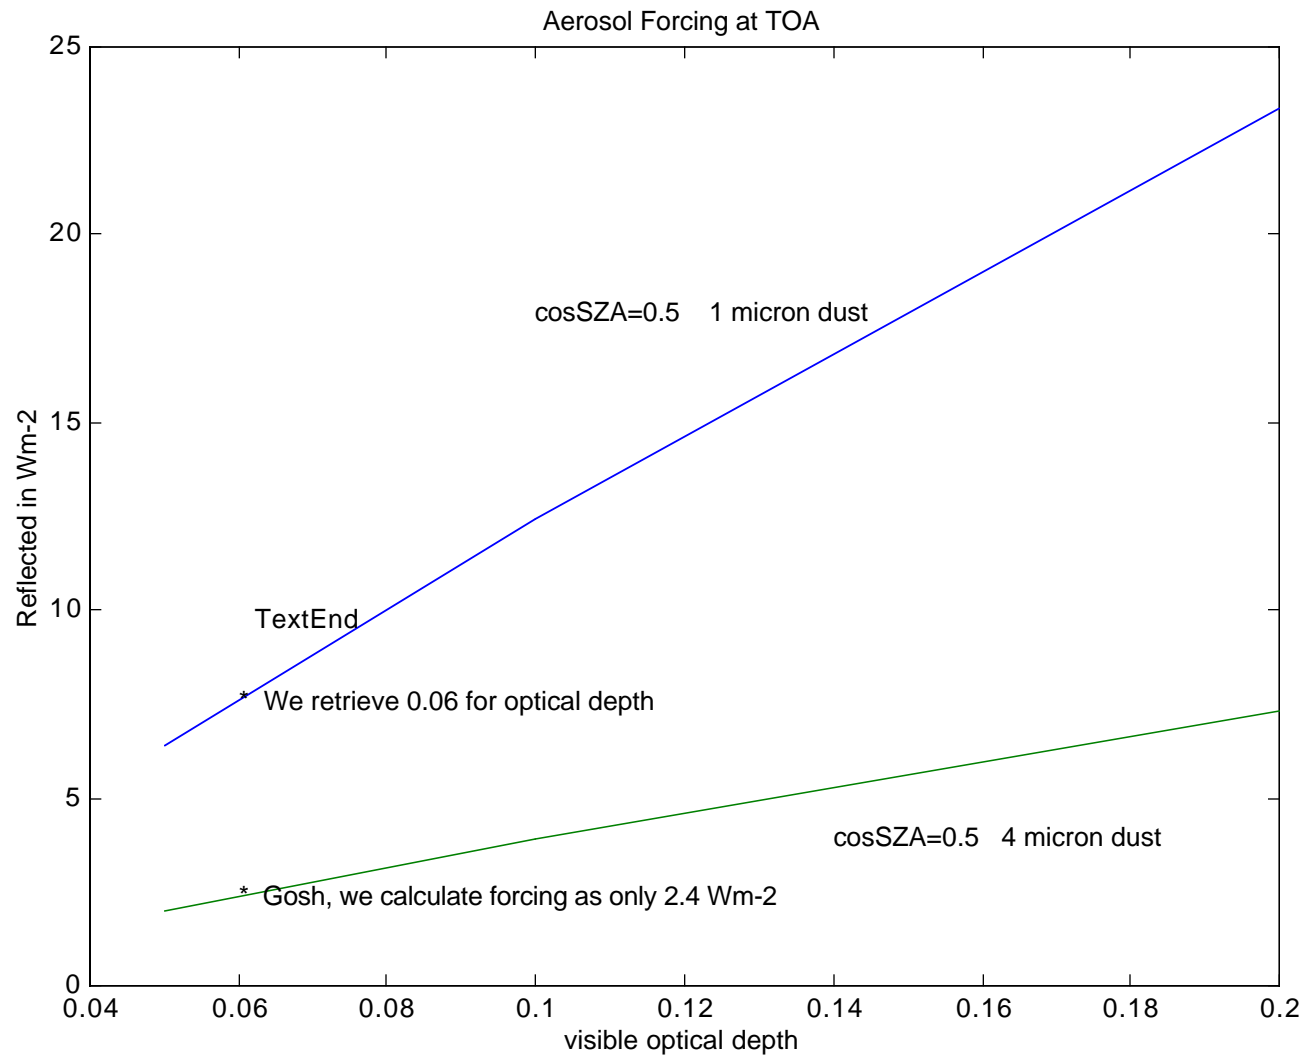

Clear sky screen (Minnis Cloud WG)

"VIRS200+" TOA SW fluxes (Loeb ADM WG)

VIRS aerosol optical thickness AOT (Stowe-Ignatov)

Fu-Liou code

Collins-Rasch assimilation

SARB output for clear-sky footprint on CRS includes:

Pu = pristeen flux, untuned (Fu-Liou calculation with no aerosols)

Cu = clear flux, untuned (Fu-Liou with aerosol)

Ct = clear flux, tuned (constrained Fu-Liou)

Co = clear flux observed by CERES

AOTu = input aerosol optical thickness (Collins-Rasch or Stowe-Ignatov)

AOTt = tuned AOT from constraintment

Three estimates of direct forcing at TOA:

F1 = Cu-Pu a raw calculation

F2 = Ct-Pu constrained estimate

F3 = Co-Pu another estimate (okay if the ocean optics are good)

AOTo = "observed" AOT that fits CERES, Fu-Liou, and assumed optical properties

$$AOTo = (Co - Pu) / (dTOA / dAOT) = (Co - Pu) / [(Cu - Pu) / AOTu]$$

Results for 1 May 2001 with "VIRS200+" ADM module

Pu = pristeen flux, untuned
Cu = clear flux, untuned with aerosol
Ct = clear flux, tuned
Co = clear flux observed by CERES

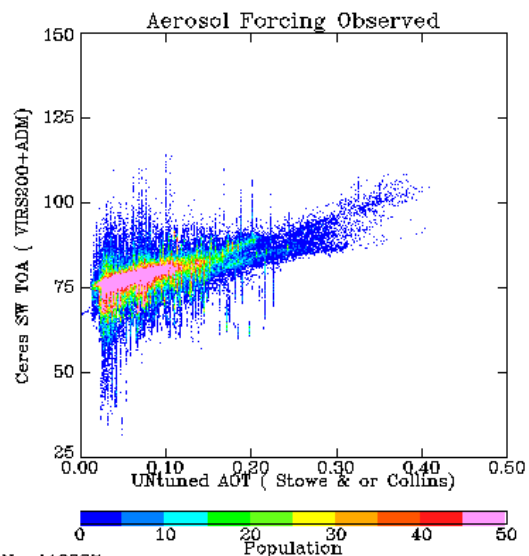

AOTu = input aerosol optical thickness (some Collins, some Stowe)
AOTt = tuned AOT from constraintment

Forcings for clear footprints with NO FORWARD SCATTERING:

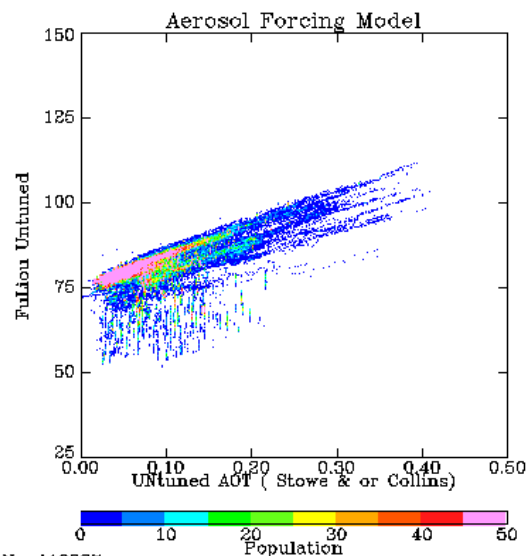

mean	insolation	type of forcing	
	weighted		
8.14 Wm ⁻²	7.81 Wm ⁻²	F1 = Cu-Pu	a raw calculation
6.38 Wm ⁻²	5.50 Wm ⁻²	F2 = Ct-Pu	constrained estimate
7.14 Wm ⁻²	5.29 Wm ⁻²	F3 = Co-Pu	another estimate

AOTo = "observed" AOT that fits CERES, Fu-Liou, and assumed optical properties

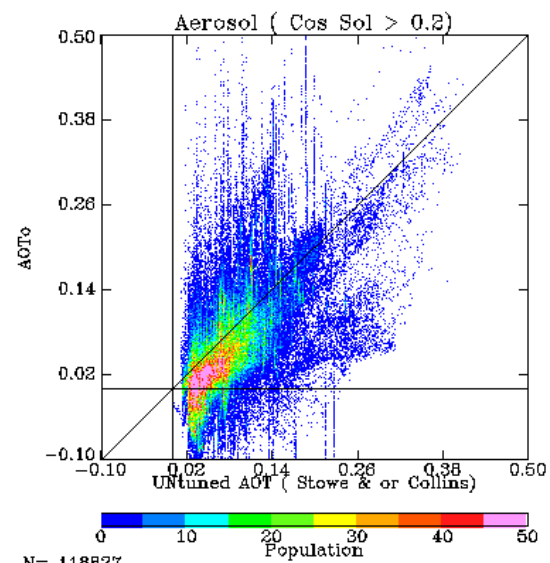

$$AOTo = (Co - Pu) / (dTOA / dAOT) = (Co - Pu) / [(Cu - Pu) / AOTu]$$
