

Land surface latent heat estimations using surface radiation data: Preliminary results

Bing Lin¹ , P. Stackhouse¹, and T.F. Fan²

¹NASA Langley Research Center, Hampton, VA

²SSAI, Hampton, VA

CERES Science Team Meeting

Fort Collins, CO

November 3-5, 2009

Goals

- **Improve land surface heat estimates**
 - combined approach
surface radiation data + model results
- **Cross-exam satellite radiation estimates**
 - water budget over land
 - river discharge

**No large scale direct observations of
land surface turbulent heat fluxes**

Land surface fluxes

differences among models are about 15 W/m^2 : all larger than surface radiation estimates.

Background

- **Model results:**
 - large bias errors for heat budget in global/large scales
- **Observations:**
 - surface radiation -- surface site val/cal may need large scale examinations
- **Radiation:** refine modeled energy balance examined by water balance

Current study (88-06)

- Radiation:
TOA & sfc -- CERES, SRB, ISCCP-FD
errors: $\sim 10 \text{ W/m}^2$
- Precipitation: GPCP
atmospheric latent heat (water balance)
annual mean errors: 5% or $\sim 4 \text{ W/m}^2$
- River discharges: ?? 10 ~ 20 % ??
- Model results: surface fluxes
interrelationships (Bowen ratio)

Land heat budget

- heat storage S
- Bowen ratio B
- forced by R_{net} daily ~ monthly time scales

$$R_{net} = LH + SH + S \quad (1)$$

$$B = LH / (LH + SH) \quad (2)$$

Large variability

SRB SFCnet Radi mean (W/m²) 1988-2004

SRB SFCnet Radi STD (W/m²)

surface net radiation

($-115 \pm 1.7 \text{ W/m}^2$; 1988 ~ 2004)

significant net radiative heating over the surface:
energy source for latent and sensible heat

surface turbulent fluxes

Ocean: HOAPS
Land: Noah

sensible heat
($18 \pm 1.9 \text{ W/m}^2$)

latent heat
($82.2 \pm 2.5 \text{ W/m}^2$)

small variability
at long temporal
scales!

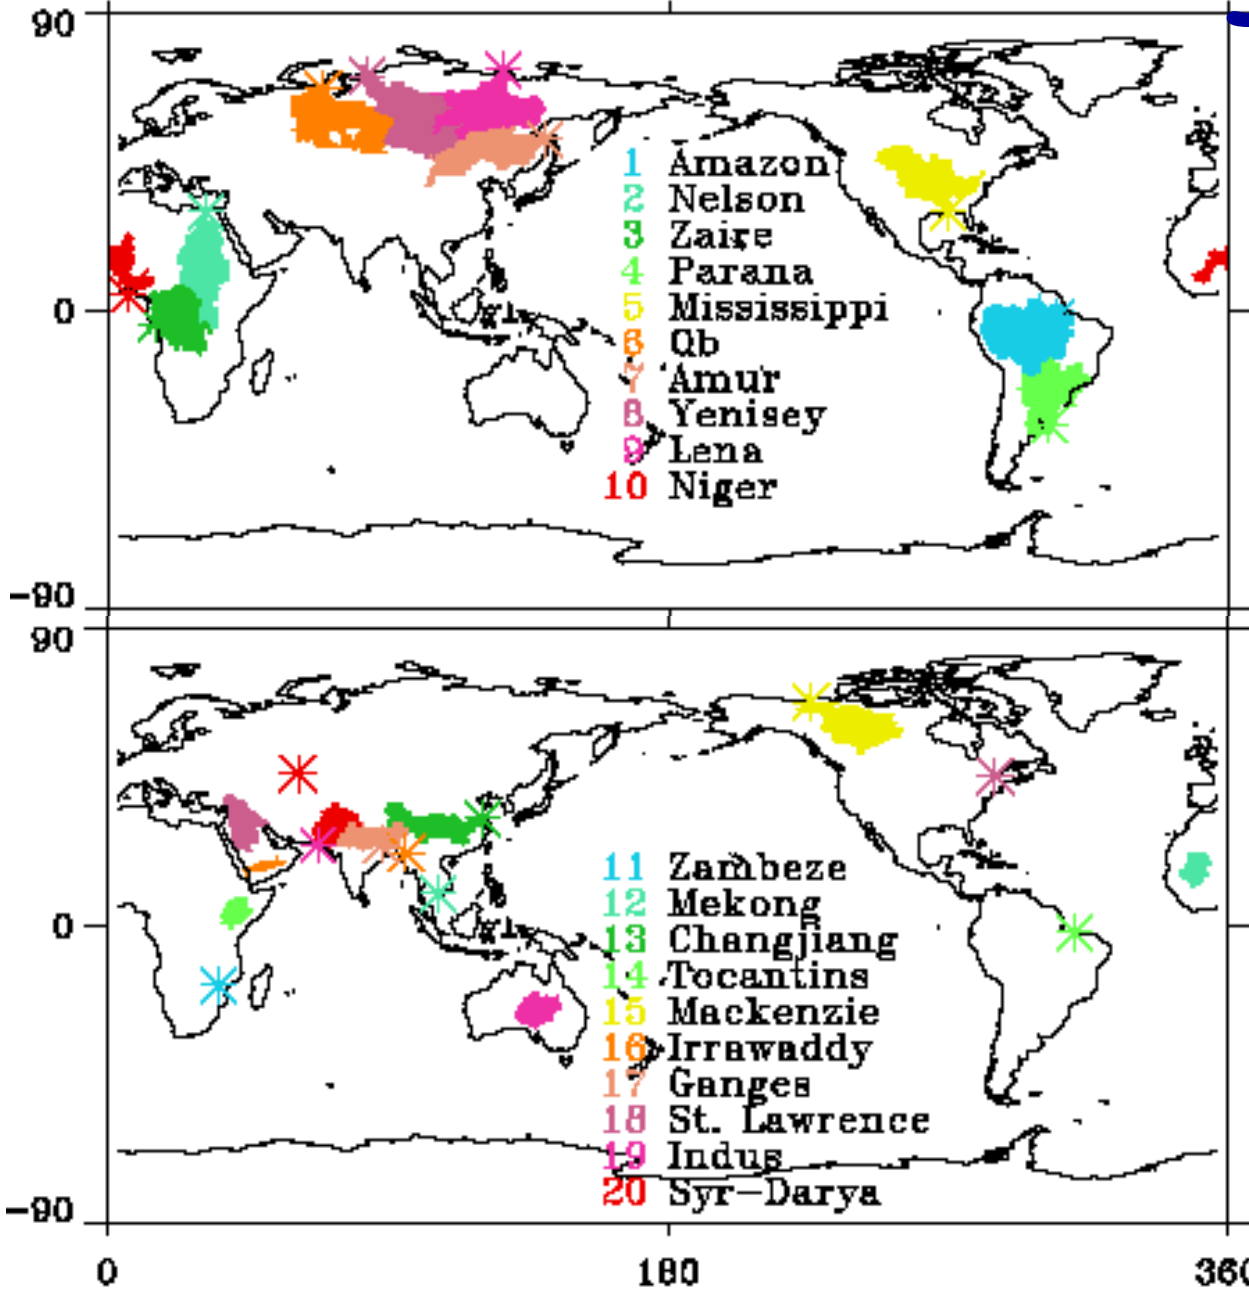

consistency and validation

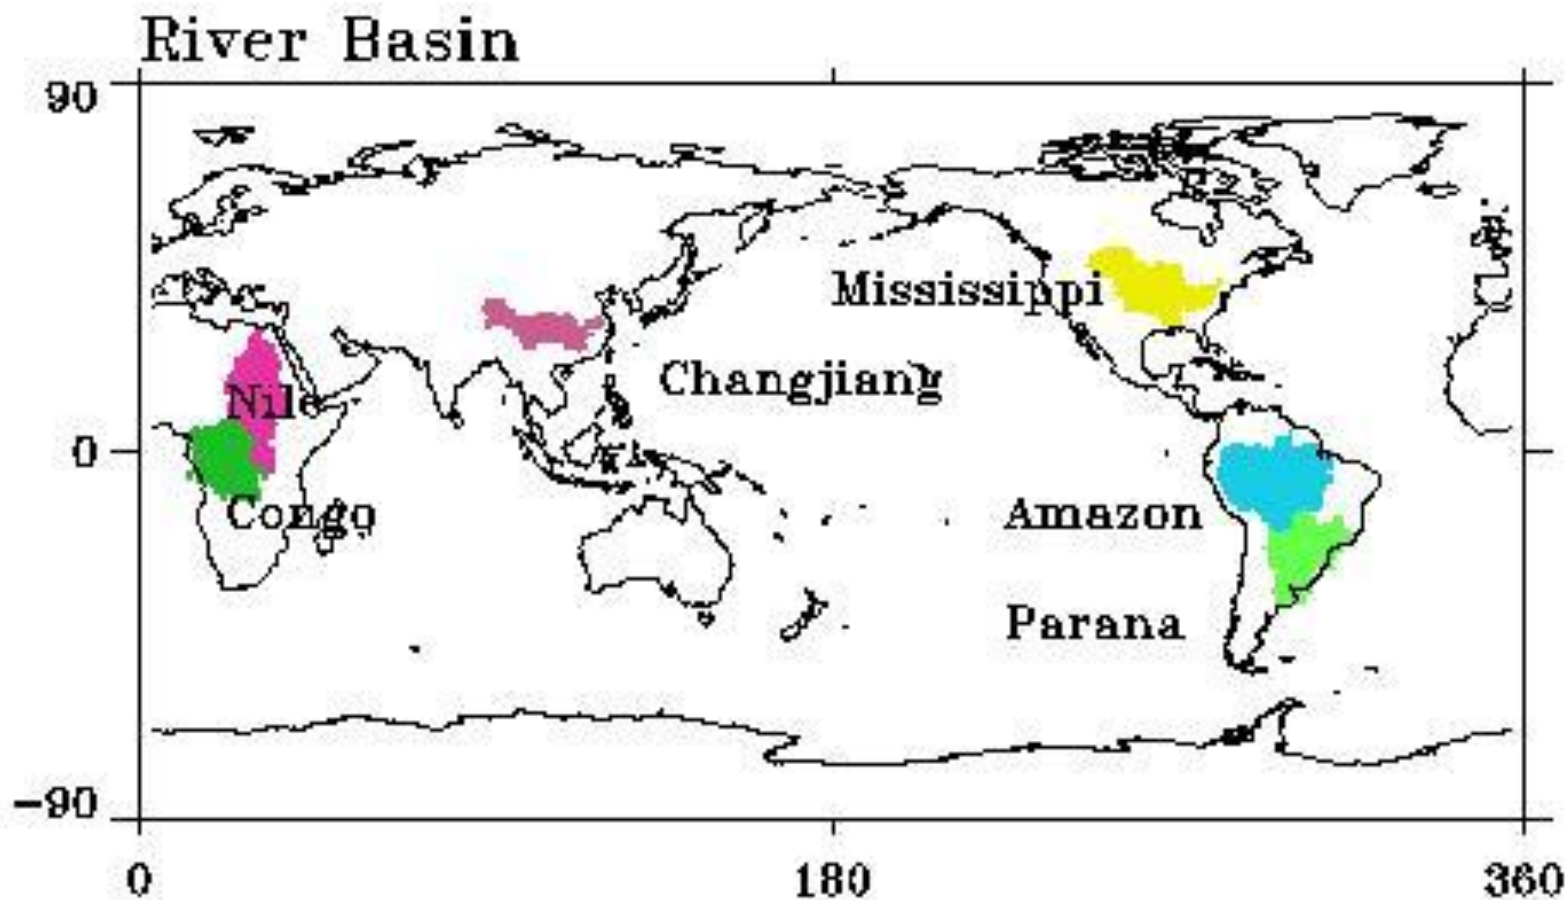

$$P - E = D + \Delta S \quad (3)$$

$$\text{long term: } \Delta S \approx 0 \quad (4)$$

river basin & discharge

focus on Mississippi & Changjiang

impoundments

Summary

- Although satellites can provide invaluable estimates of latent heat fluxes over oceans, there are significant observational gaps of the fluxes over land surfaces and cold regions.
- Current model results of land surface latent heat are considerably biased when observed radiation, precipitation and river discharge are considered. That is, modeled latent heat fluxes result in much larger imbalances in the energy and water cycles over continental or basin scales than those from observations.

Summary (conti.)

- Based on a combination of satellite surface radiation estimates and assimilation model results of land surface properties, land surface latent heat is estimated. This hybrid technique, at least, generates a consistent picture between radiative heat into land surface and the heat removed by turbulent processes.
- Comparison of estimated latent heat fluxes with satellite precipitation and river discharge observations over certain big river basins indicates that current technique may remove large bias errors. **Encourage (??)**
